FAQs

1. What is LIFO structure of stack?

Ans: LIFO means Last In, First Out. The elements in a stack are inserted and removed from the top only. Hence, the element inserted last is removed first.

2. How stack is represented?

Ans: A stack is represented using an array or a linked list.

3. What are the possible operations with stack?

Ans: The possible operations with a stack are:

PUSH() – Inserts an element into the stack.

POP() – Removes the top element from the stack.

StackEmpty() – Checks whether the stack is empty.

StackFull() – Checks whether the stack is full.

4. Explain the stack full and stack empty conditions.

Ans:

Stack Full: When `top == MAX - 1`, the stack is full.

Stack Empty: When `top == -1`, the stack is empty.

5. Explain push() function in C for stack using array.

Ans: The push() function is used to insert an element into the stack. It increases the value of top by one and stores the new element at the top position.

6. Explain pop() function in C for stack using array.

Ans: The pop() function is used to remove the top element from the stack. It returns or displays the top element and decreases the value of top by one. If the stack is empty, stack underflow occurs.

7. Explain the concept of double pointer.

Ans: A double pointer is a pointer that points to another pointer. It is declared using two asterisks.

Example: int **p;
